# EXTENDED STEREO

## Block Diagram

Zenith's extended stereo is basically quite simple and the following information should be sufficient to explain it completely. The block diagram of the extended stereo system is applicable to all models. The first portion of this system is the stereo cartridge, which will supply information from the left and right elements. The information from each channel is funnelled to each half of the automatic balance control. This automatic balance control then feeds portions of the L&R information to the mixer preamplifier stages. Out of the mixer preamplifier stages two types of information are obtained. (L+R) information or (sum information) which is funnelled to the 20 watt sum amplifier. The other type information obtained from the mixer preamplifier is (L-R) or (difference information). This is supplied to the Stereo Control which is basically a gain control for the difference channel. (L-R) information from the stereo control then goes to the 20 watt difference amplifier. The (L+R) information and the (L-R), or as we will refer to it from time to time (the stereo effect) information are then both funnelled to a matrix which electronically separates them and feeds this separated information to the left and right speakers of the stereophonic speaker system.

## Mixer Preamplifier Circuit

At first glance a system of this type would seem highly complex; however, if we clarify it, one can readily see that although ingenious in conception it is rather simple. The stereophonic cartridge consists of two elements each of which supplies voltages created by electro-mechanical process from its respective groove side. This information is fed to an automatic balance control which consists of two potentiometers ganged together physically. The information from the left channel goes to the arm of one potentiometer and the information from the right channel goes to the arm of the other potentiometer. These potentiometers are connected to the grids of the two triode halves of a 12AZ7. The arms on these potentiometers are so ganged that when the energy is increased at the grid of one triode, the energy is reduced at the grid of the other. In this manner, satisfactory balance can be obtained. In addition to being preamplifiers, these two triodes also act as a mixer system so that we can obtain the sum and difference information.

## Left Preamplifier

Closely examine the path of the signal in the left channel preamplifier, assuming we have a negative L signal supplied by the left cartridge, then at the plate of the left preamplifier, we will have positive L information, as a result of phase reversal within

the tube. For simplification in explaining the mixing action, let us assume that the left preamplifier has a gain of two, then we will have a positive 2L at the plate of this left preamplifier. This 2L information goes out through the 68K and .1 mfd. to the junction of the .1 and .047 mfd. condensers. We should stop at this moment and see what else occurs. At the plate of the left preamplifier we have a 15K and 6.8K in series which are effectively a voltage divider and at their junction we have positive L information.

## Right Preamplifier

Simultaneously, with the action in the left preamplifier negative R information is supplied by the right cartridge element and this goes to the right half of the balance control. At the high side of the right balance control L information and R information mix and we have a composite (L-R) voltage impressed on the grid of the right preamplifier. Since this voltage information is subjected to phase reversal through the tube, at the plate of the right preamplifier, we have (R-L) information.

The (R-L) information is channelled into two paths. At the junction of the 120K resistor and the .022 mfd. condenser some (R-L) information is fed to the stereo control which is basically a gain control for the (R-L) difference channel. At the junction of the 120K and .022 mfd. condenser, some of the (R-L) information goes up through 120K and the .047 mfd. condenser and mixes with the positive 2L signal from the left preamplifier. At this point, adding an (R-L) & (2L) the resultant will be (R+L) which is fed to the sum amplifier.

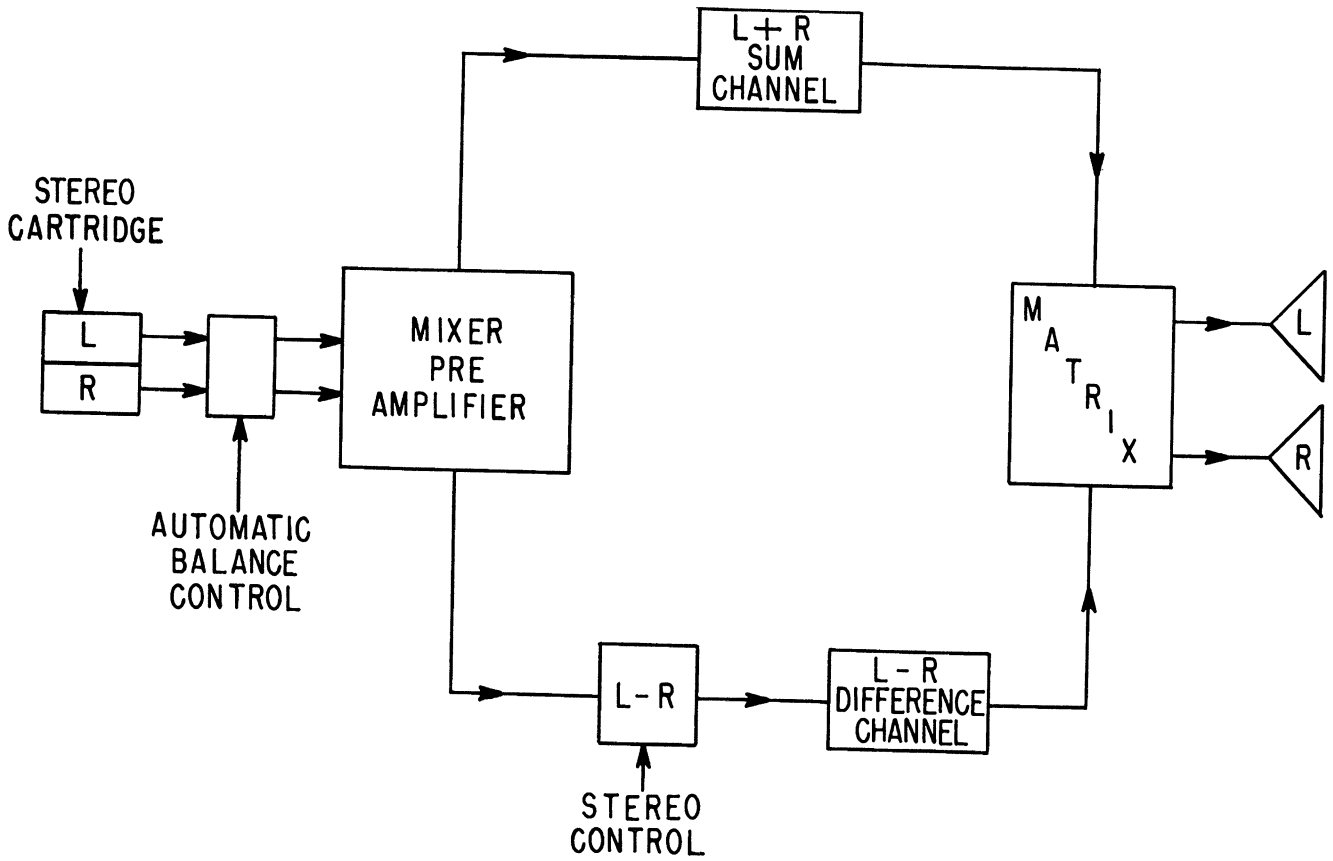

## Stereo Control

For Monaural Operation, the stereo control is in off position and we do not supply any information to the (L-R) difference amplifier, all information that passes through the system is (L+R) which is channelled to both speakers.

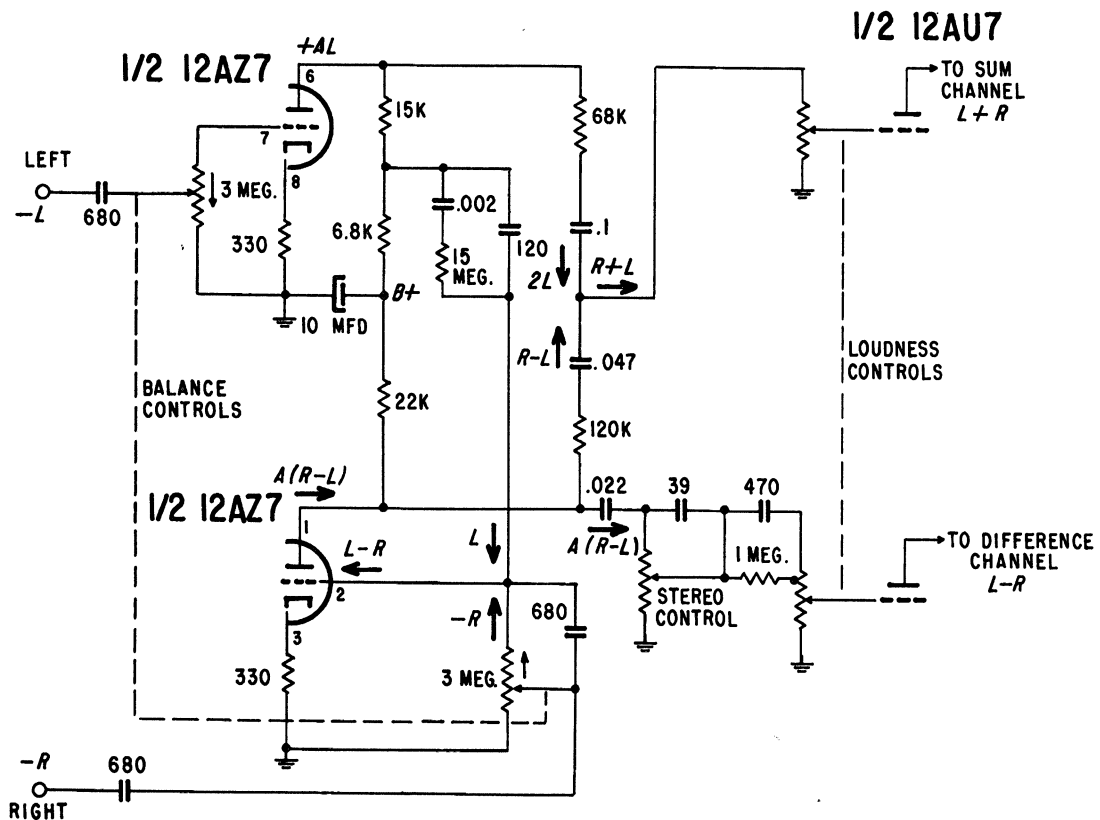

For Standard Stereo Operation, the sum amplifier and difference amplifiers are supplied with information that is equal in magnitude. Under these conditions, (L+R) and (L-R) information is supplied to the matrix with only L information arriving at the left speaker and R information arriving at the right speaker.

For Extended Stereo Operation, the energy supplied to the (L-R) or difference channel is greater

# Block Diagram for Extended Stereo Equipment

## Basic Mixer Preamplifier Circuit

than the energy supplied to the (L+R) sum amplifier. Since the loudness controls for both the sum and difference amplifiers are ganged mechanically, the gain in the amplifiers they control will always be identical.

### Matrix

At this point, we must digress and explain the matrix system. Basically the matrix system consists of two output transformers. The secondary winding of the (L-R) channel is center tapped. To this center tapped. To this center tapped secondary winding, we connect the secondary winding of the (L+R) output transformer. We now have two windings that are in series aiding or in series opposition. Again let us explain the three possible conditions at this matrix circuit.

(1) For monaural operation the L-R (difference channel) is off and without any (L-R) signal both speakers will receive (L+R) signal.

(2) For standard stereo operation, the output of the L-R (difference channel) is equal to the L+R (sum channel) and therefore by summation of the voltages from the secondary of the output transformers, which are connected in series aiding or series in opposition, L information is channelled to the L speaker and R information is channelled to the R speaker. The summation of these voltages would be as follows:

Series Aiding -

$$(L+R) + (L-R) =$$

$$L+R+L-R =$$

$$L+R+L-R=2L \text{ to the left speaker}$$

Series Opposition -

$$(L+R) - (L-R) =$$

$$L+R-L+R =$$

$$L+R-L+R=2R \text{ to the right speaker}$$

(3) For extended stereo operation under these conditions, the output of the (L-R difference channel) is greater than the output (L+R sum channel). Let us assume that we have twice the energy in the (L-R) channel than we have in the (L+R) channel. We can express this  $2(L-R)$ .

Series Aiding -

$$(L+R) + 2(L-R) =$$

$$L+R+2L-2R =$$

$$L+R+2L-2R=3L-R \text{ to the left speaker}$$

Series Opposition -

$$(L+R) - 2(L-R) =$$

$$L+R-2L+2R =$$

$$L+R-2L+2R=3R-L \text{ to the right speaker}$$

From the equation you can see in the extended stereo position, the left speaker system receives an out of phase component of right information and simultaneously the right speaker system receives an out of phase component of left information. The magnitude of the out of phase components is what determines the spread of the extended stereo system.

Basic Matrix Circuit

# R A D I A L   S O U N D   S Y S T E M

Should you have a room that will accommodate a larger speaker system and wish to improve the stereophonic reproduction, Zenith engineers have created a supplemental sound system that can be used in conjunction with these stereophonic instruments.

This equipment is the Zenith Radial Sound System, and its operation is based on the acoustical phenomena that all frequencies below 300 cycles are non-directional and that all directional properties of sound which contribute to the stereophonic spatial effect result from frequencies above 300 cycles and/or harmonics of the 300 cycles or lower frequencies that are greater than 300 cycles. As a result, all bass frequencies (300 cycles or lower) will be reproduced in the main chassis with all other frequencies coming from the two Radial Speakers.

Perhaps a review of the manner in which our ears operate as a direction finding device will be appropriate at this time. One's ability to determine direction depends entirely on the fact, that there are two ears situated on the opposite sides of the head. It is indeed fortunate that they are so located for their task.

## Time Difference

A typical example of their ability to determine direction would be as you are walking towards some friend that may be somewhat to the right of you and he shouts, your head will immediately turn to the right. Since sound travels approximately 1100 feet per second and your ears are perhaps 6 inches apart, consequently your right ear may have heard the shout  $1/2000$  of a second sooner than your left ear. This is only four hundred and fifty millionths of a second or 450 micro-seconds, but it will supply plenty of information with which your direction finding mechanism can work. Normal human ears can detect time differences as small as 6 micro-seconds. As we all know, our intricate mental computers read the amounts and type of delay and tell us almost instantly the direction of the sound source.

## Phase Discrimination

Another important characteristic of sound is its wavelength. Sound travels approximately 1100 feet per second. Assume we have a thousand cycle frequency, we therefore have one thousand compressions and decompressions per second. Then the distance in air between two compressions must be just a little more than 1 foot. This is the wavelength of a thousand cycle frequency. Plainly the wavelength varies inversely with frequency. A frequency of 100 cycles per second has a wavelength of 11 feet. A frequency of 300 cycles per second has a wave-

length of 3.66 feet. Since the wavelength of frequencies 300 cycles or lower is 3.66 feet and greater, then the difference in air compression or rarefaction at the two ears separated by only inches will be infinitesimal compared to the change over a full cycle. This method of locating sounds is phase discrimination. It is ineffective at frequencies below 300 cycles and very effective between 300 to approximately 1600 cycles per second.

## Intensity

Somewhat below the upper limit of 1600 cycles per second another characteristic of sound begins to furnish information. Sound will normally flow around an object when the object is much smaller than the wavelength of the sound, however, when the wavelength of the sound approaches or becomes smaller than the object, then the side of the object away from the sound is in shadow and the intensity becomes less at the far side. The ear on the side of the head away from the sound source is in shadow and receives the sound less intensely.

Our ears do not use these various facilities singly but simultaneously. The fact that both Time Difference and Phase Discrimination both fail with continuous low frequency sound is the basis on which the Radial Sound System functions.

Now that some of the various factors upon which Zenith's Radial Sound is based have been explained, we shall compare a previous dual channel full stereophonic amplifier to a similar model equipped with the Radial Sound System. On the model SF2505, each channel has a display system consisting of one 12 inch woofer and one 5 inch tweeter. On the model SFD2505, each audio display system will also be equipped with a 12 inch woofer and a 5 inch tweeter. However, each channel will in addition have a special socket to accept a Radial Sound System which consists of a tweeter, a midrange speaker, and a frequency filter network.

The customer will purchase the SFD2505 without the Radial Sound System, and will use it as a standard stereophonic instrument. Then if he wishes to convert to the Radial Sound System, he can purchase the two supplementary speaker systems and connect them to the sockets provided on the SFD2505. When they are connected, the tweeter speakers in the master or bass unit SFD2505 are disconnected, and the filtering in the supplementary speaker system will only feed frequencies 300 cycles or lower to the woofer speakers in the SFD2505.

All frequencies above 300 cycles and all harmonics of the 300 cycle or lower frequencies that are greater than 300 cycles are funnelled to the new supplementary speakers. A system of this type will greatly enhance the stereophonic effect and will eliminate the need for the usual small area center listening position.

# GENERAL

## Automatic Frequency Control (AFC)

Some of these receivers feature an automatic frequency control which automatically keeps your receiver on the exact station frequency when you are tuned to an FM station. To utilize this feature tune the receiver as instructed and then turn the band switch to (AFC) position.

When the desired FM station is a weak station, adjacent in frequency to a strong station, the AFC may pull the tuning into the stronger station. Under these conditions, place the band switch in FM position and tune the receiver as instructed.

Tuning the receivers on the frequency modulation band will require more care than on the broadcast band. A hissing sound may be noted when tuning between Frequency Modulation stations. This is normal, and will disappear as the station is tuned in. After a station is located, the pointer should be moved back and forth over it until the point of quietest reception and best tone quality is found. Correct tuning is indicated by the disappearance of background noise.

## AM and FM Alignment

The AM and FM IF transformers in these receivers are of the new permeability tuned type. The advantage of an IF transformer of this type is its extreme stability under various humidity and temperature conditions. The upper coil is the secondary and the lower the primary. When adjusting these IF transformers the tuning wrench 68-26 can be inserted into the top slug, rotated until maximum output is obtained and then dropped down to the lower slug and the same operation repeated. The tuning wrench is so designed that turning one slug does not effect the adjustment of the other.

## FM IF Alignment

Because of the wide band pass, it is desirable to use a FM signal generator and a cathode ray oscilloscope when aligning the FM IF channel. The instruction book for the Zenith Model 800 Signal Generator (Form Z8001) covers complete FM alignment procedure. If visual alignment equipment is unavailable, reasonably accurate alignment can be made by following the procedure outlined below.

## FM Discriminator Alignment

When the secondary of the discriminator is aligned use sufficient signal input to get a good positive and negative indication before setting the slug for zero reading. A center zero indicating meter is recommended for this adjustment, but is not absolutely necessary. Reversing the leads of a non-zero center

meter, or observing closely when the meter starts to go to the left (negative) of zero will give the same results.

## FM RF Alignment

The tuning slugs are attached to threaded shafts and the slugs are varied in the field of the coils by turning the shafts clockwise or counterclockwise. After adjustment the shafts must be secured with a drop of speaker cement.

## IMPORTANT

Alignment of this chassis will in most cases be unnecessary unless an IF or RF transformer is replaced or the adjustments have been tampered with.

Correct alignment can only be made by using the following procedure:

A vacuum tube voltmeter with an isolation resistor of 2,000,000 ohms in series with the hot lead will serve for FM adjustments. This lead should be shielded.

An AC output meter connected across the primary or secondary of the output transformer will be satisfactory for all AM adjustments.

The signal generator output should be kept just high enough to get an indication on the meter.

(a) Vacuum Tube Voltmeter Lug 7 on discriminator transformer to chassis (half discriminator load).

(b) Vacuum Tube Voltmeter Lug 5 on discriminator transformer to chassis (full discriminator load).

(c) Vacuum Tube Voltmeter from limiter grid to chassis.

(d) Loosen slugs by applying a hot iron to the cement.

## Automatic Balance Control

To obtain equal audio output from each channel adjust the automatic balance control in the following manner:

1. Rotate the stereo control until the indicator on the monaural stereo dial is in standard stereo position.
2. Play a monophonic record.
3. Adjust the automatic balance control so the sound appears to come from a point midway between the two speakers.

## Cartridge Connections

The wires to the stereo cartridge should be connected as follows: "Red" wire to "R" terminal of cartridge, "Black" to "middle" terminal and "White" wire to "L" terminal of cartridge.

## 6BQ5 Balance Control

On some chassis if one or both of the 6BQ5 output tubes in each final audio amplifier are replaced, it will be necessary to connect a DC volt meter across the balance terminals and adjust the balance control for minimum voltage.

## Speaker Phasing

It is most important that coded speaker leads be connected to coded terminals on speakers for proper polarity within each speaker group. It is also then most important that the speaker groups be in phase with each other. One excellent method to determine if the speaker groups are in phase is to play a monaural record as described under Automatic Balance Control.

Under these conditions the sound should appear to come from a point midway between the two speaker groups. If the sound comes from any other point than midpoint, then one speaker group is out of phase with the other and you should check polarity. One of the easiest methods of checking polarity within the speaker group is to momentarily place a 4½ volt battery across the speaker feed terminals. All the speaker cones should simultaneously move in the same direction.

## Coaxially Mounted Tweeters

On models SFD220, SFD283, SFD285 and SFD288, the 5¼ inch tweeters are coaxially mounted within one of the 12 inch woofer speakers.

## DPS-80

An excellent method to determine if the speaker groups are in phase with each other is to play a monophonic record and then adjust the balance control until the sound appears to come from a point midway between the two speaker systems. If the sound comes from any other point, then one speaker group is out of phase with the other and you should check their polarity.

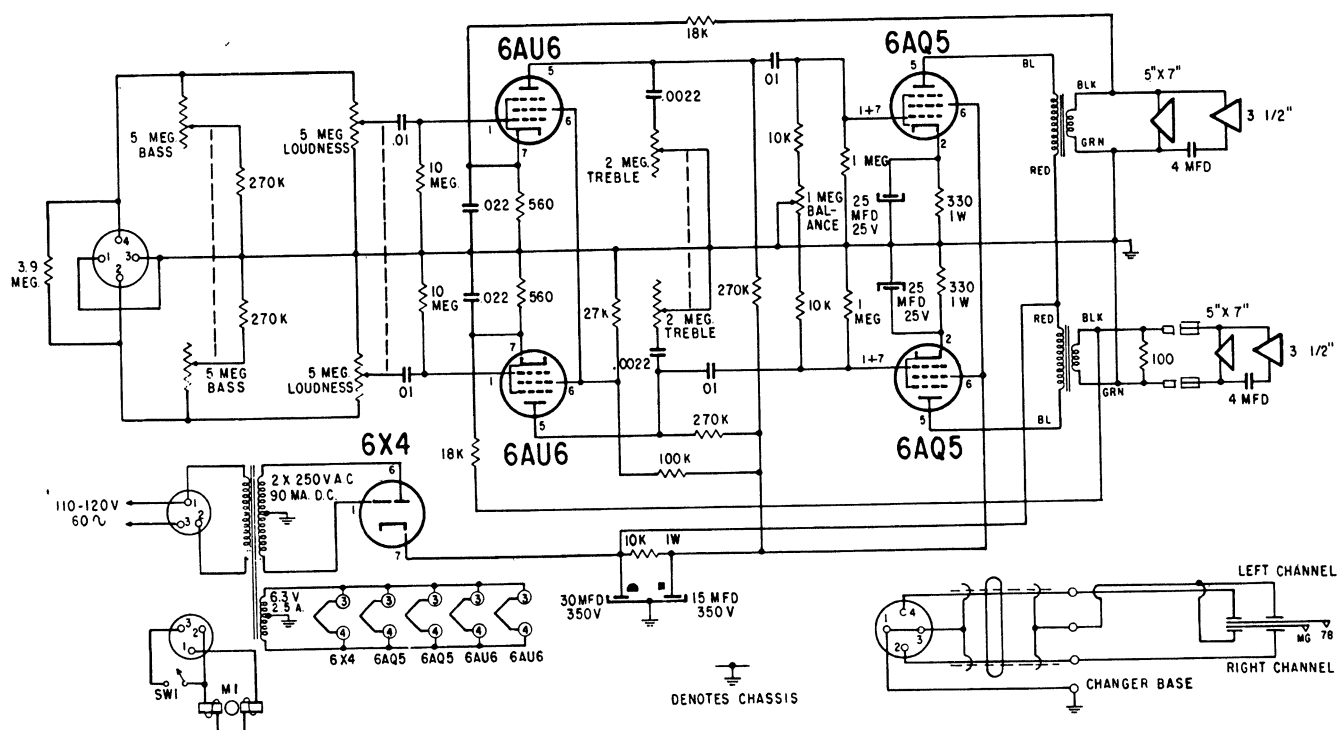

## DPS-89 ---DRS-89

An excellent method to determine if the speaker groups are in phase with each other is to play a monophonic record with the tone controls on both amplifiers in mid position and then adjust the loudness controls until the sound appears to come from a point midway between the two amplifiers. If the sound comes from any other point, then one speaker group is out of phase with the other and you should check polarity.

In the event tubes are changed or someone should misadjust the balance controls on either of the chassis, the adjustment of either one or both balance controls may be required. Proceed in the following manner: On both the master and remote instruments, place the loudness controls in position 3, then using a monophonic record on the changer, adjust the balance control on either chassis until the output appears to come from a point midway between the two speaker systems.
